

1. `exec()` is a member of the `exec` family of system calls in Linux. Replace the current process image with a new program. Instead of continuing the original C program, the process becomes the echo program.
2. Ex. First `printf()` runs normally.
2. `exec()` replaces the program with `bin/echo`.
3. `bin/echo` prints
Hello from exec.
The second `printf()` will not execute.
3. Because when `exec()` succeeds, it does not return the process memory is replaced completely by the new program that time only runs if `exec()` fails.
4.
 - `exec()` fails
 - It returns -1.
 - execution continues to the next line.
5. If commented out or removed `exec()` both `printf` statements will run normally.
